Section 2.1 C++11

Default Member Init

 \oplus

For any member m that has a default member initializer, constructors that don't initialize m in their member initializer list will implicitly initialize m by using the default member initializer value:

Note that initialization of all data members including those using the default member initializers happen in the order in which they are **declared** in the class **definition**. Accordingly, previously initialized nonstatic data members can be used in subsequent initializer expressions:

The default member initializer, just like member function bodies and member initialization lists, executes in a complete-class context. Since the initializer sees its enclosing class as a complete type, it can therefore reference the size of the enclosing type and invoke member functions that have not yet been seen:

```
struct S5
{
    int d_a[4];
    int d_i = sizeof(S5) + seenBelow(); // OK
    int seenBelow();
};
```

 \oplus

Name lookup in **default member initializers** will find **members** of the enclosing class and its bases before looking in namespace scope:
