Generalized PODs '11

reinterpret_cast from one pointer type to another or from one **reference type** to another is valid, so long as the **cast** does not drop a **cv-qualifier** (which would be ill **formed**). It is only an *access* through the pointer or reference that might be invalid, leading to **undefined behavior**. The general rule is that an access to an object through the result of a **reinterpret_cast**<T*> is valid if and only if an object of type T exists at that address at the time it is accessed. Most of the pitfalls described below are violations of this concise, general, and widely applicable rule.

1. Using reinterpret_cast for object conversions — A reinterpret_cast operates between pointer types, between reference types, between pointer-to-member types, and between pointer types and integral types, but not between other object types. It is ill formed to use reinterpret_casts to perform type conversions, even among types for which conversions exist. We cannot, for example, reinterpret_cast an int to a float or vice versa, nor can we reinterpret_cast a prvalue such as 3.14 to a reference of any kind:

```
struct Class1 { explicit Class1(int); }; // explicitly convertible from int
```

| float | rc1 = | reinterpret_cast <float>(3);</float> | | 1, | / Err | or |
|---------------|-------|--|------|-----|-------|-------------|
| int | rc2 = | <pre>reinterpret_cast<int>(3.0);</int></pre> | | 1, | / Err | or |
| const double& | rc3 = | <pre>reinterpret_cast<const double&="">(3.</const></pre> | 14); | 1 | / Err | or |
| int&& | rc4 = | <pre>reinterpret_cast<int&&>(3.14);</int&&></pre> | | 1, | / Err | or, prvalue |
| int | rc5 = | reinterpret_cast <int>(3);</int> | | 1, | ⁄ ОК, | no-op |
| unsigned | rc6 = | reinterpret_cast <unsigned>(3);</unsigned> | | 1, | / Err | or |
| Class1 | rc7 = | <pre>reinterpret_cast<class1>(5);</class1></pre> | | 1, | / Err | or |
| | | | | | | |
| float | sc1 = | <pre>static_cast<float>(3);</float></pre> | 11 | ОΚ, | but | unnecessary |
| int | sc2 = | <pre>static_cast<int>(3.0);</int></pre> | 11 | ОΚ, | | |
| const double& | sc3 = | <pre>static_cast<const double&="">(3.14);</const></pre> | // | ОΚ, | | |
| int&& | sc4 = | <pre>static_cast<int&&>(3.14);</int&&></pre> | 11 | ОΚ, | temp | orary obj |
| int | sc5 = | <pre>static_cast<int>(3);</int></pre> | 11 | ОΚ, | no-c | р |
| unsigned | sc6 = | <pre>static_cast<unsigned>(3);</unsigned></pre> | 11 | ОΚ, | but | unnecessary |
| Class1 | sc7 = | <pre>static_cast<class1>(5);</class1></pre> | 11 | 0K | | |

Note that all of the ill_formed uses of reinterpret_cast above are valid uses of static_cast.

2. Accessing objects of unrelated types via reinterpret_cast — Although reinterpret_cast between incompatible pointer and reference types is always valid, undefined behavior can arise when attempting to dereference such a converted pointer or reference: Unless there is somehow a valid object of the appropriate type at that address, accessing a value stored there has undefined behavior.

To illustrate the austerity of this rule, consider that even though two different trivial standard-layout types, e.g., A and B below, might have precisely the same layout
